Odontometric Sexual Dimorphism: A Sibling Correlation

SONALI SHARMA¹, AJIT D DINKAR², SUMIT BEDI³

ABSTRACT

Aims and Background: Teeth form an excellent material for anthropological, genetic, odontologic and forensic investigations. The aim of this study was to establish the genetic control of sexual dimorphism in tooth size amongst siblings of Goan children in age range of 14-22 years.

Materials and Methods: Twenty-two sibling pairs were selected (22 males and 22 females) to assess genetic control of sexual dimorphism in tooth size. Alginate impressions were obtained for maxillary and mandibular arches and study models were prepared. Measurements were done using Zoom Digimatic Vernier Calipers with a resolution of 0.01 mm.

Statistical Analysis: Correlation between mesiodistal and buccolingual tooth sizes amongst siblings was calculated using Pearson's correlation coefficient.

INTRODUCTION

The mouth has fittingly been identified as the organ system, “where it all begins”. For, in the final Forensic analysis, the human dentition may have “the last word” [1]. Forensic science relies upon use of teeth and jaws as a means of identification. Teeth are more likely to survive trauma than any other part of the body [2]. They can be used for gender identification as difference in tooth size between males and females is seen amongst members of the same family [3-5]. Genetic control of sexual dimorphism through the assessment of mesiodistal and buccolingual tooth dimensions in sibling pairs has been rarely reported. The lack of such studies in Indian subcontinent gave the impetus for the study.

MATERIALS AND METHODS

The present study was conducted in the Oral Medicine, Diagnosis & Radiology Department, Goa Dental College and Hospital, India from 2007 to 2008, to establish genetic control of sexual dimorphism in tooth dimensions. Twenty-two sibling pairs were selected (22 males and 22 females) in the age range from 14 to 22 years to assess genetic control of sexual dimorphism in tooth size.

Inclusion criteria for the study were patients/ students in the age range of 14 to 22 years with fully erupted, healthy and non-worn out teeth. Exclusion criteria were a history of severe illnesses / a history of prior severe illnesses / a history of previous orthodontic treatment and extraction.

After the ethical clearance from institutional ethical committee and informed consent from all the study subjects were obtained, maxillary and mandibular impressions were obtained in suitable sized beaded trays with Alginite Impression material (Zhermack Tropicalgin Chromatic). After impression disinfection, study models were prepared with Type II dental stone and labeled.

The measurements were done using Zoom Digimatic Vernier Calipers with a least count of 0.01mm. All the measurements namely the Mesio-Distal Widths and the Bucco-Lingual Widths of maxillary and mandibular teeth were carried out according to the methodology adopted by Garn SM et al., [3-5]. Size assessment of the corresponding permanent teeth in the maxillary and mandibular arches was done amongst the respective siblings.

STASTICAL ANALYSIS

Geometric mean was calculated for mesiodistal and buccolingual dimensions of all the teeth amongst siblings. Pearson correlation coefficient was used to analyze the degree of correlation which is indicated by the symbol ‘r’ and is referred to as the r-value. A positive value indicated the strength of the association. A p-value <0.05 was considered significant.

RESULTS

Mesiodistal Widths of Maxillary and Mandibular Teeth amongst Siblings

A statistically significant association was found between Mesiodistal Widths of Permanent Maxillary Right and Left Second Molars and between Maxillary Right and Left First Premolars amongst sibling pairs. A statistically significant association was also found between Buccolingual Widths of Mandibular Right and Left First Premolars amongst sibling pairs. This statistically significant correlation found amongst siblings establishes a genetic control over sexual dimorphism in these teeth.

Buccolingual Widths of Maxillary and Mandibular Teeth amongst Siblings

A statistically significant association was also found between Buccolingual Widths of Mandibular Right and Left First Premolars (r-value: 0.451, 0.469 at a p-value of 0.035 & 0.028) amongst sibling pairs. A statistically significant association was found between Mesiodistal and Buccolingual Widths of Mandibular Right and Left First Premolars amongst sibling pairs.

Keywords: Mesiodistal tooth dimensions, Buccolingual tooth dimensions, Correlation Coefficient
dental maturation, by sex for the first primary molars [8]. Subba RV concluded that sexual dimorphism is seen in eruption of Permanent dentition as girls tend to exhibit early eruption and development when compared to boys [9].

Sweet D stated that the teeth are the hardest substances in the human body as they can survive most of the insults and consequences encountered at death and during decomposition [2]. Bletcher SR and Erickson RP wrote that in most mammals, including humans, males have larger teeth than females and this was also evident in the deciduous teeth of humans. This sexual dimorphism was ascribed to a locus, TSY, on the Y chromosome. They concluded that many and possibly all tissues bear the imprint of their genetic sex [10].

Garn SM et al., conducted studies on two hundred and forty three Ohio subjects to evaluate the sexual dimorphism in tooth size in more than one hundred sibling pairs [3-5]. Due to lack of similar studies in Indian population, the present study was taken up to assess genetic basis of sexual dimorphism in Goan Indian children. The positive correlation obtained amongst siblings clearly ascertains the genetic control of sexual dimorphism in teeth.

The First Premolars showed significant correlation between the sibling pairs mesiodistally as well as buccolingually which establishes the existence of dimorphism amongst these teeth. This is in correlation with the results obtained by Garn SM et al who found that teeth adjacent to the mandibular canine share with it a tendency for greater percentage dimorphism.3-5 In contrast, control group showed dimorphism in canines.

CONCLUSION
The genetic basis of sexual dimorphism in human dentition was ascertained as a significant correlation was found between Mesio-Distal and Bucco-Lingual Widths of premolar teeth between genetically related individuals i.e. sibling pairs. The role of Forensic Odontologist as a part of the Forensic team cannot be underestimated.

ACKNOWLEDGEMENTS
I would like to acknowledge the contribution of all the study subjects, whose cooperation made this study possible. I would also like to thank Dr. M.S.Kulkarni, Department of Preventive and Social Medicine, Goa Medical College and Hospital, for doing the statistical analysis for the present study.
